Abstract: Muscle tissue of 145 sika deer (*Cervus nippon*) collected in Tokyo Metropolis and surrounding regions in southern Kanto were investigated based on mitochondrial D-loop sequences. Four (CN-1-CN-4) of the nine identified haplotypes (CN-1-CN-9) accounted for 94.5% of the total study population. One (CN-1) of these four haplotypes was widely distributed throughout the whole study region, but the other 3 haplotypes (CN-2, CN-3, CN-4) were locally distributed in different areas of the region. Two (CN-2, 3) of these haplotypes were distributed around the Kanto Mountains, whereas the other (CN-4) was around the Tanzawa Mountains. All 6 individuals sampled in Hachioji City, a new habitat area that sika deer in Tokyo Metropolis have recently entered, possessed the haplotype found locally around the Kanto Mountains. Thus, we concluded that the deer captured in Hachioji City have been originated from the Kanto Mountains.

Key-word: habitat expansion, D-loop region, haplotype, Kanto Mountains

要旨: 東京都および周辺で捕獲された計 145 個体のニホンジカの筋肉片サンプルを用いてミトコンドリア DNA の D-loop 領域の多型解析を行った。ハプロタイプは、9 タイプ(CN-1~CN-9)検出され、そのうち 4 タイプが全体の 94.5%を占めていた。これら 4 タイプは、比較的広域に分布する CN-1 タイプと偏域的に分布する CN-2、CN-3、CN-4 タイプに二分された。このうち偏域分布する 3 タイプのうち、CN-2 および CN-3 タイプは関東山地周辺に分布し、CN-4 タイプは丹沢山地周辺に分布していた。都内の生息拡大域にあたる八王子市において捕獲された 6 個体は、すべて関東山地のハプロタイプを有していた。このことから、八王子市に定着したニホンジカは、関東山地個体群がソースとなっていると考えられた。

キーワード: 生息域拡大, D-loop 領域, ハプロタイプ, 関東山地

I Introduction

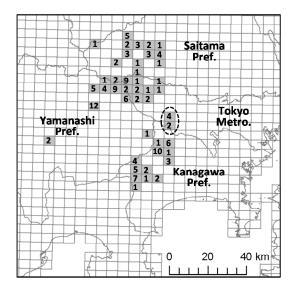

Fig.1. Sample locations. Numbers indicate sample size in each mesh (5×5km). The dashed line indicates the recently expanded habitat area in Hachioji City.

Sika deer (*Cervus nippon*) cause extensive damage to areas that are being reforested. In Tokyo Metropolis, forest damage due to overpopulated sika deer has been a longstanding problem. This overpopulation has serious ramifications, such as an incident in Okutama Town in 2004, in which the sediment blocked the drinking water supply brought about by a run-off from denuded mountainsides undergoing reforestation. This incident prompted the metropolitan authorities to formulate management measures such as Sika Deer Conservation and

Management Plan to control sika deer populations. Although the sika deer population density decreased and stabilized due to the population control policy, the population has increased again in recent years resulting in deer being sighted in Hachioji City where they previously did not occur (Fig.1.). For example, in 2013, camera traps belonging to the Tokyo Metropolitan Agriculture and Forestry Research Center photographed a sika deer in Hachioji City that had been ear-tagged previously in the Tanzawa Mountains in Kanagawa Prefecture (unpublished). Thus, an understanding of sika deer migration routes is necessary to mitigate further expansion of sika deer into areas where they did not occur previously.

Therefore, in this study we sought to clarify the genotypes of sika deer in Tokyo Metropolis and surrounding regions, and sought to determine the origin of individual deer captured in Hachioji City.

II Materials and methods

We used 145 sika deer samples used in Konishi *et al.* (2017) (3). Muscle tissue samples were collected from 139 sika deer between 2013 and 2014 in Tokyo and the surrounding regions; namely Tokyo Metropolis, Saitama, Kanagawa and Yamanashi prefectures. In addition, samples were also collected from 6 deer in Hachioji City, Tokyo Metropolis, in 2015 where sika deer have been expanding their habitats in recent years. Total DNA was extracted based on the phenol/proteinase K/sodium dodecyl sulfate method, with a slight modification. Then, the Mitochondrial D-loop regions (approximately 1,100 bp) were amplified by polymerase chain reaction (PCR). Three primers

were used to amplify and sequence the D-loop regions; L15926 and H597 designed by Nagata et al. (4) and a supplemental primer we designed for this study (5'-ATGCTTGGACTCA GCAATGG-3'). The PCR products were purified using Exo SAP-IT (Affymetrix), and then these products were used as template for direct sequencing. The sequencing was carried out using an automated sequencer 3130xl Genetic Analyzer (Applied Biosystems), and the sequence alignment was performed using MEGA 6.0 computer software (6). The D-loop region of sika deer contains tandem repeats, each of which consists of approximately 40 bp motifs. The repetition of these units differs greatly between populations (5), so these regions were deleted for the present sequence analysis.

III Results and discussion

We compared the nucleotide sequences of mtDNA D-loop regions from the 145 sika deer and identified nine haplotypes (Table 1.). The most frequent haplotype was designated as CN-1 (46.2%), followed by CN-2 (20.7%), CN-3 (14.5%), CN-4 (13.1%), CN-5 (2.1%), CN-6 (1.4%), CN-7 (0.7%), CN-8 (0.7%), and CN-9 (0.7%). Haplotypes CN-1 to CN-4 accounted

for 94.5% of the total study population, whereas haplotypes CN-5 to CN-9 were each identified in only one to three deer. CN-1 was identical to sequences previously reported in deer in Tochigi Prefecture (AB500007 and AB500008; Registered region include tandem repeat region that is excluded in this study). The CN-6 haplotype, identified in two deer in this study, was identical to a haplotype from Tanegashima Island, Kagoshima Prefecture (AB757723) (7). These two deer with the CN-6 haplotype were considered to be immigrants, based on records of sika deer being imported and released in Kanagawa Prefecture (2).

The geographical distribution of the nine haplotypes is shown in Figure 2. The CN-1 haplotype was widely distributed across the study area, whereas the CN-2, CN-3, and CN-4 haplotypes were locally distributed in different regions. Specifically, the CN-2 and CN-3 haplotypes were distributed around the Kanto Mountains; north of the Sagami River, whereas the CN-4 haplotype was distributed around the Tanzawa Mountains; south of the Sagami River. Genetic divergence between deer from the Tanzawa Mountains and the Kanto Mountains have been identified previously by short sequence repeat (SSR)

analysis (3).

The CN-2 haplotype was found in four of the six sika deer samples collected from Hachioji City, while the other individuals had the CN-3 haplotype. Since the CN-2 and CN-3 haplotypes are characteristic of deer from the Kanto Mountains, it seems that the deer captured in Hachioji City originated from these Mountains. Five of these six sika deer were female. It is known that females tend to be observed later than males in an immigration phase (1). We concluded that sika deer originating from the Kanto Mountains have now settled in Hachioji City.

However, since an ear-tagged male deer from the Tanzawa Mountains was photographed in Hachioji City in 2013 (unpublished), it is virtually assured some sika deer to move from Tanzawa Mountains to Tokyo Metropolis. Further monitoring is needed to estimate the influence of the Tanzawa Mountain population on Tokyo population. We think that the analysis of sika deer migration source presented in this study will help future collaborative efforts by municipal and regional authorities to manage the sika deer population.

IV Conclusions

- 1. Four of the nine D-loop haplotypes identified in the present study accounted for 94.5% of the analyzed sika deer population; one haplotype was widely distributed (CN-1) and three were locally distributed (CN-2, CN-3, and CN-4).
- 2. The CN-2 and CN-3 haplotypes were locally distributed in the Kanto Mountains, and the CN-4 haplotype was distributed in the Tanzawa Mountains.
- 3. The six deer captured in Hachioji City where the population of sika deer has recently expanded into contained haplotypes of Kanto Mountains (CN-2 or CN-3). We consider that the deer captured in Hachioji City have been originated from the Kanto Mountains.

Acknowledgments

We thank Dr. Hayato Iijima of the Yamanashi Forest Research Institute, Dr. Toru Taniwaki of the Kanagawa Prefecture Natural Environment Conservation Center, Mr. Mutsumi Ohkawara of the Saitama Prefectural Agriculture and Forestry Research Center, officials of the Water Resources Administration Office (Bureau of Waterworks, Tokyo Metropolitan Government), Dr. Takayuki Seto and the many hunters for providing samples of sika deer. We also thank Dr. Iain McTaggart for his editorial assistance. This research is supported by The Tokyu Foundation for Better Environment.
